

# IMPROVING THE MICROSCOPIC PARTICULATE ANALYSIS

Peter Wallis

Hyperion Research Ltd., Medicine Hat, AB

# Why is this important?

In the post-Walkerton era, Canadian regulations in several Provinces require that all wells used as potable sources must be tested for surface water intrusion.

**Cow pasture, flooded during the spring rains**

**Under Canadian regulations in some provinces an investigation of every well used as a potable water source must be carried out by a qualified hydrogeologist**

Phase I – Initial screening for risk factors such as distance to surface water

Phase II – Hydrogeological investigation including chemistry, well logs etc.

Phase III - Microscopic Particulate Analysis as specified by (EPA Consensus Method 910/9-92-029).

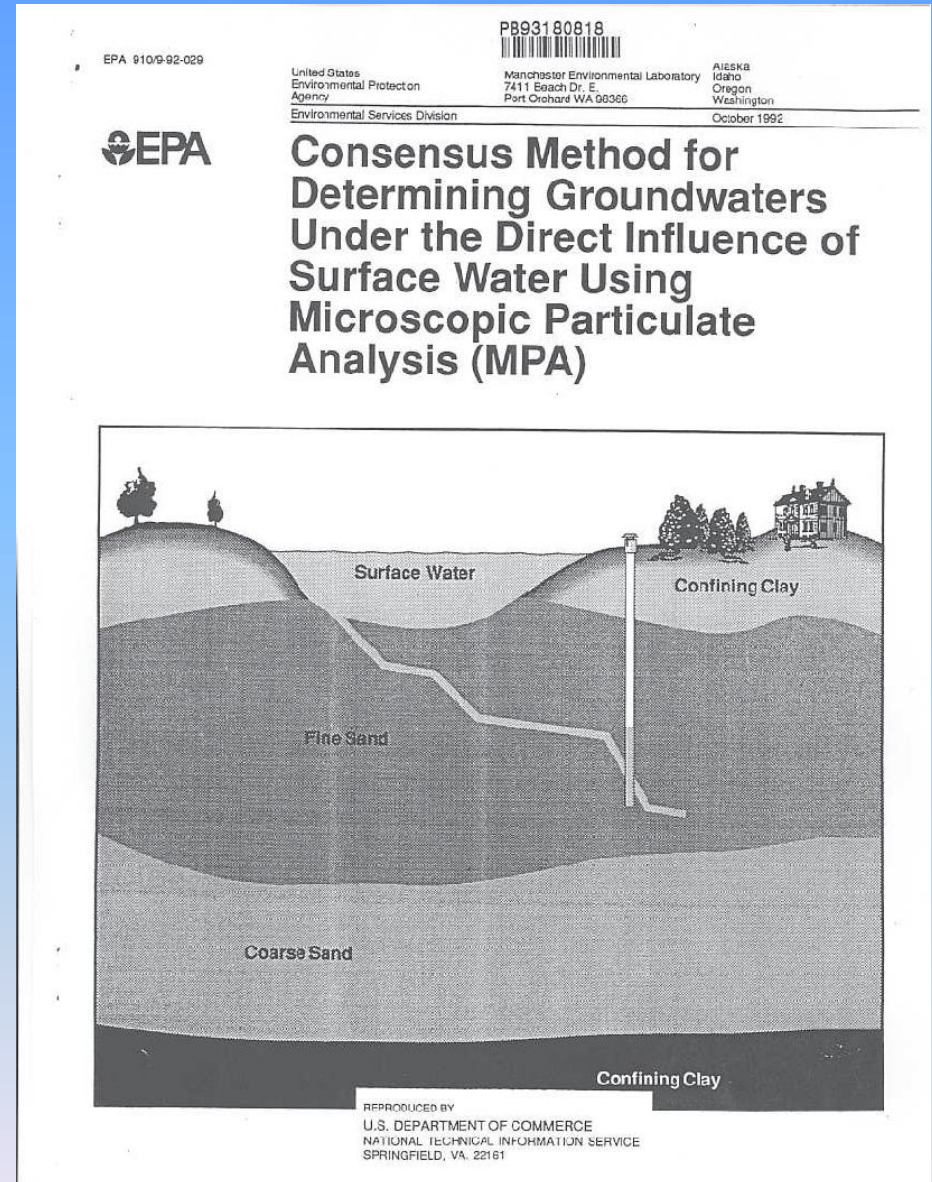

Nice cap!

**Unfortunately, the Consensus MPA method has several drawbacks including:**

- **Old filter technology (string wound cartridges)**
- **Inefficient recovery of particles**
- **Large filtration volume means extended field time**
- **Lack of quality control protocol**

**Problems can be overcome!**

The Consensus method was based on the original string-wound cartridge method for *Giardia* and *Cryptosporidium*.

This method has been superseded by Method 1623

Method 1623 specifies:

- much better filters which can be eluted more efficiently
- immunomagnetic separation to recover cysts and oocysts
- a rigorous quality control protocol

Additional benefits include:

- Much lower filtration volumes saving time in the field
- Smaller pellets for examination
- Ability to work at much higher pressures (Filta-Max)

Why not modify the existing protocol to Method 1623?

# Lab testing apparatus

Recovery of *Giardia* cysts, *Cryptosporidium* oocysts and *Euglena gracilis* cells by the **Consensus** method in a complex matrix containing clay, precipitated iron and background minerals

1. According to EPA "Guidance Manual for Compliance with the Filtration and Disinfection Requirements for Public Water Systems Using Surface Water Sources", March 1991 ed.
2. Refer to Table 1 for range of indicators counted per 100 gallons.  
Key= EH -extremely heavy M -moderate NS -not significant  
H -heavy R -rare
3. Risk of surface water contamination:  
≥20 - high risk  
10-19 - moderate risk  
≤9 - low risk

Plant debris

Rotifer

Pollen in groundwater

# UNDER THE MICROSCOPE

## Primary Particulates

## Secondary Particulates

# Spores/L in two wells and surface water

# Risk calculated for two Maritime wells

# Conclusions

- **The Microscopic Particulate Analysis is a useful tool in determining whether groundwater is under the influence of surface water**
- **Recovery of particulate matter is inefficient with string-wound filters**
- **Method 1623 offers much better detection of the primary pathogens *Giardia* and *Cryptosporidium* and the pellet can be used for surface water organism detection**
- **Higher efficiency of particulate recovery means lower volumes need to be filtered resulting in reduced field sampling costs**
- **A quality control procedure is needed and already exists for Method 1623**
- **Higher recovery efficiency means that the risk tables need to be recalibrated**
- **High sediment background is still a problem**
- **Aerobic spore forming bacteria are an inexpensive addition to the MPA**
- **Nearby surface water should be sampled along with well water**
